PROJECT OVERVIEW · OCTOBER 2026

Medical Research Briefing

Type in a medical condition. Get a clear, fully referenced briefing on how it is treated today, which treatments are being developed, and who is developing them.

The problem today

- Information is spread across medical journals, drug approval records and clinical trial registries
- Pulling it together by hand takes a lot of analyst time, for every condition
- General AI chatbots can make up drugs, studies and references, which is unacceptable in healthcare

What we set out to do

- One search produces one structured briefing
- Use only trusted, public medical sources
- Never make anything up
- Keep approved treatments apart from experimental ones
- Show problems openly, never hide them

HOW IT WORKS

Gather, draft, then fact-check

1. Gather

The software searches three trusted public sources:

- **PubMed**: treatment guidelines and research reviews
- **FDA drug labels**: approved medicines
- **ClinicalTrials.gov**: studies under way

2. Draft

An AI model (OpenAI) reads only what was gathered and writes each section in plain language.

It is told to use nothing else and to reference every point.

3. Check

The software checks every reference against the records it gathered and removes anything it cannot confirm.

The AI writes; it never decides what is true.

Each briefing contains

Executive summary	Standard of care today	Treatments in development	Companies and institutions	Linked references

WHY YOU CAN TRUST IT

Built so that nothing is made up

Every reference is checked

Each study, drug label or trial cited must match a record found in that same search. Anything else is removed.

Facts come from official records

A trial’s stage, status, sponsor and dates are copied from the registry, never written by the AI.

Approved vs experimental

Today’s care uses only guidelines and FDA labels. Treatments in development use only active trials and are labelled “Investigational”.

No evidence, no claim

If a source finds nothing, the briefing says so instead of guessing. An approved drug tested in a new combination is flagged as such.

Problems shown openly

One source down: briefing marked “Partial”. All down: no briefing at all. A missing login is flagged before you start.

Every removal is listed

A “data quality notes” panel shows reviewers exactly what was removed and why.

WHAT WE TESTED

Tested on a real lung cancer case

41
automated checks, all passing

30/30
lung cancer trials matched the official registry

5/5
deliberately planted errors caught and removed

20
issues found by testing and fixed

What the lung cancer search found

- 8 current treatment guidelines, including NCCN and ASCO
- 20 FDA-approved drugs for the condition
- 30 active late-stage trials, each confirmed in the registry

Examples of what testing caught

- An outage was shown as “nothing found”: now labelled clearly
- One slow source could stop everything: now reported alone
- A drug label excerpt cut off the lung cancer use: now fixed

Also tested: empty results, services down or slow, missing or wrong login details, and the app showing each state · 4

STATUS AND NEXT STEPS

Where we are and what comes next

Ready now

- Working app that runs on a laptop
- Three trusted sources connected
- Fact-checks and safeguards in place
- Briefings download as documents

Still to confirm

- AI writing not yet run with our OpenAI account; testing used a stand-in
- References are checked automatically; wording is guided by rules
- Covers the 30 most recently updated late-stage trials

Next steps

1. Add the OpenAI key; run lung cancer end to end
2. Expert review of the first briefings
3. Test set of conditions to track quality
4. Save results to speed up repeat searches

Every claim in a briefing traces back to a source found in that search, or it is not shown.
